ABSTRACT

Specifying and implementing a proof system from scratch requires significant effort. Logical Frameworks and Higher Order Logic Programming Languages provide dedicated, high-level Meta Languages (ML) to facilitate this task in two key ways: 1) variable binding and substitution are simplified when ML binders represent object logic ones; 2) proof construction, and even proof search, is greatly simplified by leveraging the unification procedure provided by the ML. Notable examples of ML are Elf [13], Twelf [15], λProlog [9] and Isabelle [21] which have been utilized to implement various formal systems such as First Order Logic [3], Set Theory [12], Higher Order Logic [11], and even the Calculus of Constructions [2].

The object logic we are interested in is Coq's [19] Calculus of Inductive Constructions (CIC), for which we aim to implement a unification procedure $\simeq_o$ using the ML Elpi [1], a dialect of λProlog. Elpi's equational theory comprises $\eta\beta$ equivalence and comes equipped with a higher order unification procedure $\simeq_\lambda$ restricted to the pattern fragment [8]. We want $\simeq_o$ to be as powerful as $\simeq_\lambda$ but on the object logic CIC. Elpi also comes with an encoding for CIC that works well for meta-programming [18, 17, 6, 4]. Unfortunately this encoding, which we refer to as $\mathcal{F}_o$, "underuses" $\simeq_\lambda$ by restricting it to first-order unification problems only. To address this issue, we propose a better-behaved encoding, $\mathcal{H}_o$, demonstrate how to map unification problems in $\mathcal{F}_o$ to related problems in $\mathcal{H}_o$, and illustrate how to map back the unifiers found by $\simeq_\lambda$, effectively implementing $\simeq_o$ on top of $\simeq_\lambda$ for the encoding $\mathcal{F}_o$.

1 INTRODUCTION

Meta languages such as Elf [13], Twelf [15], λProlog [9] and Isabelle [21] have been utilized to specify various logics [3, 11, 12, 2]. The use of these meta languages facilitated this task in two key ways. The first and most well know one is that variable binding and substitution come for free. The second one is that these meta languages come equipped with some form of unification, a cornerstone in proof construction and proof search.

The object logic we are interested in is Coq's [19] Calculus of Inductive Constructions (CIC) and we want to implement a form of proof search known as type-class [20, 16] resolution. In particular we want to leverage the Elpi [18] meta programming language, a dialect of λProlog already used to extend Coq in various ways [18, 17, 6, 4]. Type-class solvers are unification based proof search procedures reminiscent of Prolog that back-chain lemmas taken from a designated database of "type class instances", hence we can expect that Elpi is a good fit for implementing such as form of automation. In this paper we focus on one aspect of this work, namely *how to reuse the higher order unification procedure of the meta language in order to implement a type-class solver for the object language.* As it turns out, re-using the unification of the meta language is not a trivial task.

We take as an example the `Decision` and `Finite` type classes from the Stdpp [7] library. The class `Decision` identifies predicates equipped with a decision procedure, while `Finite` the types whose inhabitants can be enumerated in a (finite) list. The following three designated `Instances` state that: 1) the type `fin n`, of natural numbers smaller than `n`, is finite; 2) the predicate `nfact n nf`, linking a natural number `n` to the number of its prime factors `nf`, is decidable; 3) the universal closure of a predicate has a decision procedure if its domain is finite and if the predicate is decidable.

```
Instance fin_fin: ∀n, Finite (fin n).                 (* r1 *)
Instance nfact_dec: ∀n nf, Decision (nfact n nf). (* r2 *)
Instance forall_dec: ∀A P, Finite A →                 (* r3 *)
  ∀x:A, Decision (P x) → Decision (∀x:A, P x).
```

Given this database a type-class solver is expected to prove the following statement automatically:

```
Decision (∀x: fin 7, nfact x 3)                      (* g *)
```

The proof found by the solver back-chains on rule 3 (the only rule about the ∀ quantifier), and then solves the premises with rules rules 1 and 2 respectively. Note that rule 3 features a second order parameter `P` that stands for a function of type `A → Prop` (a predicate over `A`). The solver has to infer a value for `P` by unifying the conclusion of rule 3 with the goal, and in particular by solving the unification problem `P x = nfact x 3`. This higher order problem falls in the so called pattern-fragment $\mathcal{L}_\lambda$ [8] and hence admits a unique solution `P =` λ`x.nfact x 3`.

In order to implement such a search in Elpi we shall describe the encoding of CIC terms and then the encoding of rules. Elpi comes

Conference'17, July 2017, Washington, DC, USA

ACM ISBN 978-x-xxxx-xxxx-x/YY/MM
https://doi.org/10.1145/nnnnnnn.nnnnnnn

with an Higher Order Abstract Syntax [14] datatype of CIC terms, called `tm`, that features (among others) the following constructors:

```
type lam  tm -> (tm -> tm) -> tm.      % lambda abstraction
type app  list tm -> tm.               % n-ary application
type all  tm -> (tm -> tm) -> tm.      % forall quantifier
type con  string -> tm.                % constants
```

Following λProlog [9]'s standard syntax, the meta level binding of a variable `x` in an expression `e` is written «`x\ e`», and square brackets denote a list of terms separated by comma. For example the term «`∀y:t, nfact y 3`» is encoded as follows:

```
all (con"t") y\ app[con"nfact", y, con"3"]
```

We now illustrate the encoding of the three instances above as higher-order logic-programming rules: capital letters denote rule parameters; `:-` separates the rule's head from the premises and `pi w\ p` introduces a fresh nominal constant `w` for the premise `p`.

```
finite   (app [con"fin", N]).                          (r1)
decision (app [con"nfact", N, NF]).                    (r2)
decision (all A x\ app [P, x]) :- finite A,            (r3)
  pi w\ decision (app [P, w]).
```

Unfortunately this intuitive encoding of rule $(r3)$ does not work, since it uses the predicate `P` as a first order term: for the meta language its type is `tm`. If we try to back-chain the rule $(r3)$ on the encoding of the goal g given below

```
decision (all (app [con"fin", con"7"]) y\              (g)
  app [con"nfact", y, con"3"]).
```

we obtain an unsolvable unification problem (p): the two lists of terms have different lengths!

```
app [con"nfact", y, con"3"] = app [P, y]               (p)
```

In this paper we study a more sophisticated encoding of rules that, on a first approximation, would shape $(r3)$ as follows:

```
decision (all A x\ Pm x) :- link Pm P A, finite A,     (r3')
  pi x\ decision (app [P, x]).
```

Since `Pm` is an higher-order unification variable of type `tm -> tm`, with `x` in its scope, the unification problem (p') admits one solution:

```
app [con"nfact", y, con"3"] = Pm y                     (p')
Pm = x\ app [con"nfact", x, con"3"]                    (ρ)
```

Once the head of rule $(r3')$ unifies with the goal (g) the premise «`link Pm A P`» brings the assignment (ρ) back to the domain `tm` of Coq terms:

```
P = lam A a\ app [con"nfact", a, con"3"]
```

This simple example is sufficient to show that the encoding we seek is not trivial and does not only concern the head of rules, but the entire sequence of unification problems that constitute the execution of a logic program. In fact the solution for `P` above generates a (Coq) β-redex in the second premise (the predicate under the `pi w\`). We show below the premise before and after the instantiation of `P`:

```
decision (app[                P                      , w])
decision (app[ lam A (a\ app [con"nfact", a, con"3"]) , w])
```

In turn this redex prevents the rule $(r2)$ to backchain properly since the following unification problem has no solution:

```
app[ lam A (a\ app [con"nfact", a, con"3"]) , x] =
app[ con"nfact"                             , N, NF]
```

The root cause of the problems we sketched in this example is a subtle mismatch between the equational theories and unification procedures of the meta language and the object language.

The equational theory of CIC is very rich. In addition to the usual $\eta\beta$-equivalence for functions, terms (hence types) are compared up to proposition unfolding and fixpoint unrolling. Still, for efficiency and predictability reasons, most form of automatic proof search employ a unification procedure that captures a simpler one, just $\eta\beta$, and that solves higher-order problems restricted to the pattern fragment $\mathcal{L}_\lambda$. We call this unification procedure $\simeq_o$.

The equational theory of the meta language Elpi is strikingly similar, since it it comprises $\eta\beta$ (for the meta language functions), and the unification procedure $\simeq_\lambda$ solves problems in $\mathcal{L}_\lambda$ as well.

In spite of the similarity the link between $\simeq_\lambda$ and $\simeq_o$ is not trivial, since the abstraction and application term constructors the two unification procedures deal with are different.

Contributions. In this paper we identify a minimal language $\mathcal{F}_o$ in which the problems sketched in the introduction can be formally described. We detail an encoding of a logic program on $\mathcal{F}_o$ to a strongly related logic program in $\mathcal{H}_o$ (the language of the meta language) and we show that the unification procedure of the meta language $\simeq_\lambda$ can be effectively used to simulate a unification procedure $\simeq_o$ for the object language that features $\eta\beta$-conversion in the pattern-fragment. fix

section 2 formally states the problem and gives the intuition behind our solution. section 9 discusses alternative term encodings and related works. section 3 introduces the languages $\mathcal{F}_o$ and $\mathcal{H}_o$, section 4 describes a basic simulation of higher order logic programs. sections 5 and 6 completes its equational theory with support for η-conversion. section 7 deals with the practical necessity of "tolerating" terms outside of the pattern-fragment and discusses how heuristic can be applied. Finally section 8 discusses the implementation in Elpi.

The λProlog code discussed in the paper can be accessed at the URL: https://github.com/FissoreD/paper-ho.

2 PROBLEM STATEMENT AND SOLUTION

Even if we encountered the problem working on CIC we devise a minimal setting to ease its study. In this setting we have a $\mathcal{F}_o$ language (for first order) with a rich(er) equational theory and a $\mathcal{H}_o$ meta language with a simpler one, and we reuse the unification procedure of $\mathcal{H}_o$ in order to implement one for $\mathcal{F}_o$.

2.1 Preliminaries: $\mathcal{F}_o$ and $\mathcal{H}_o$

In order to reason about unification we provide a description of the $\mathcal{F}_o$ and $\mathcal{H}_o$ languages where unification variables are first class terms, i.e. they have a concrete syntax as per fig. 1. Unification variables (`fuva` term constructor) in $\mathcal{F}_o$ have no explicit scope: the arguments of an higher order variable are given via the `fapp` constructor. For example the term «`P x`» is represented as «`fapp[fuva N, x]`», where `N` is a memory address and `x` is a bound variable.
In $\mathcal{H}_o$ the representation of «`P x`» is instead «`uva N [x]`», since

```
kind fm type.                         kind tm  type.
type fapp list fm -> fm.              type app list tm -> tm.
type flam (fm -> fm) -> fm.           type lam (tm -> tm) -> tm.
type fcon string -> fm.               type con string -> tm.
type fuva addr -> fm.                 type uva addr -> list tm -> tm.
```

Figure 1: The $\mathcal{F}_o$ and $\mathcal{H}_o$ languages

unification variables are higher order and come equipped with an explicit scope.

Notational conventions. When we write $\mathcal{H}_o$ terms outside code blocks we follow the usual λ-calculus notation, reserving f, g, a, b for constants, x, y, z for bound variables and X, Y, Z, F, G, H for unification variables. However we need to distinguish between the "application" of a unification variable to its scope and the application of a term to a list of arguments. We write the scope of unification variables in subscript while we use juxtaposition for regular application. Here a few examples:

$f \cdot a$	`app [con "f", con "a"]`
$\lambda x.\lambda y.F_{xy}$	`lam x\ lam y\ uva F [x, y]`
$\lambda x.F_x \cdot a$	`lam x\ app [uva F [x], con "a"]`
$\lambda x.F_x \cdot x$	`lam x\ app [uva F [x], x]`

When it is clear from the context we shall use the same syntax for $\mathcal{F}_o$ terms (although we never subscripts unification variables).

We use $s, s_1, \ldots$ for terms in $\mathcal{F}_o$ and $t, t_1 \ldots$ for terms in $\mathcal{H}_o$.

2.2 Equational theories an unification

In order to specify unification we need to define the equational theory and substitution (unification-variable assignment).

2.2.1 Term equality: $=_o$ and $=_\lambda$. For both languages we extend the equational theory over ground terms to the full language by adding the reflexivity of unification variables (a variable is equal to itself).

The first four rules are common to both equalities and just define the usual congruence over terms. Since we use an HOAS encoding they also capture α-equivalence. In addition to that $=_o$ has rules for η and β-equivalence.

```
type (=o) fm -> fm -> o.                                  (=o)
fcon X =o fcon X.
fapp A =o fapp B :- forall2 (=o) A B.
flam F =o flam G :- pi x\ x =o x => F x =o G x.
fuva N =o fuva N.
flam F =o T :-                                            (ηl)
  pi x\ beta T [x] (T' x), x =o x => F x =o T' x.
T =o flam F :-                                            (ηr)
  pi x\ beta T [x] (T' x), x =o x => T' x =o F x.
fapp [flam X | L] =o T :- beta (flam X) L R, R =o T.      (βl)
T =o fapp [flam X | L] :- beta (flam X) L R, T =o R.      (βr)
```

```
type (=λ) tm -> tm -> o.
con C =λ fcon C.
app A =λ fapp B :- forall2 (=λ) A B.
lam F =λ flam G :- pi x\ x =λ x => F x =λ G x.
uva N A =λ fuva N B :- forall2 (=λ) A B.
```

The main point in showing these equality tests is to remark how weaker $=_\lambda$ is, and to identify the four rules that need special treatment in the implementation of $\simeq_o$. For brevity we omit the code of beta: it is sufficient to know that «`beta F L R`» computes in `R` the weak head normal form of «`app[F|L]`».

Substitution: ρs and σt. We write $\sigma = \{ X \mapsto t \}$ the substitution that assigns the term t to the variable X. We write σt for the application of the substitution to a term t, and $\sigma X = \{ \sigma t \mid t \in X \}$ when X is a set of terms. We write $\sigma \subseteq \sigma'$ when σ is more general than σ'. The domain of a substitution is the set of unification variables for which it provides an assignment. We write $\sigma \cup \sigma'$ set union to denote the concatenation of two substitutions whose domains are disjoint. We shall use ρ for $\mathcal{F}_o$ substitutions, and σ for the $\mathcal{H}_o$ ones. For brevity, in this section we consider the substitution for $\mathcal{F}_o$ and $\mathcal{H}_o$ identical. We defer to section 3 a more precise description pointing out theirs differences.

can be made a little more formal

Term unification: $\simeq_o$ vs. $\simeq_\lambda$. Although we provide an implementation of $\simeq_\lambda$ in the supplementary material (that we used for testing purposes) we only describe its signature here.

```
type (≃λ) tm -> tm -> subst -> subst -> o.
```

The meta language of choice is expected to provide an implementation of $\simeq_\lambda$ that satisfies the following properties:

$$\{t_1, t_2\} \subseteq \mathcal{L}_\lambda \Rightarrow t_1 \simeq_\lambda t_2 \mapsto \rho \Rightarrow \rho t_1 =_\lambda \rho t_2 \quad (1)$$

$$\{t_1, t_2\} \subseteq \mathcal{L}_\lambda \Rightarrow \rho t_1 =_\lambda \rho t_2 \Rightarrow \exists \rho', t_1 \simeq_\lambda t_2 \mapsto \rho' \wedge \rho' \subseteq \rho \quad (2)$$

We write $\sigma t_1 \simeq_\lambda \sigma t_2 \mapsto \sigma'$ when σt_1 and σt_2 unify with substitution σ'. We write $t_1 \simeq_\lambda t_2 \mapsto \sigma$ when the initial substitution is empty. Note that if $\sigma t_1 \simeq_\lambda \sigma t_2 \mapsto \sigma'$ then the domains of σ and σ' are disjoint.

Although we provide an implementation of $\simeq_o$ in section 4.4, our real goal is the simulation of an entire logic program.

2.3 The problem: Logic Program Simulation

We represent a logic program *run* in $\mathcal{F}_o$ as a list *steps* p of length $\mathcal{N}$. At each step p we unify two terms $\mathbb{P}_{p_l}$ and $\mathbb{P}_{p_r}$ taken from the set of all terms $\mathbb{P}$. [1] The composition of these steps starting from the empty substitution ρ_0 produces the final substitution $\rho_\mathcal{N}$, that is the result of the logic-program execution.

$$\text{fstep}(\mathbb{P}, p, \rho) \mapsto \rho'' \stackrel{def}{=} \rho\mathbb{P}_{p_l} \simeq_o \rho\mathbb{P}_{p_r} \mapsto \rho' \wedge \rho'' = \rho \cup \rho'$$

$$\text{frun}(\mathbb{P}, \mathcal{N}) \mapsto \rho_\mathcal{N} \stackrel{def}{=} \bigwedge_{p=1}^{\mathcal{N}} \text{fstep}(\mathbb{P}, p, \rho_{p-1}) \mapsto \rho_p$$

In order to simulate a $\mathcal{F}_o$ logic program in $\mathcal{H}_o$ we compile each term $s \in \mathcal{F}_o$ into a term $t \in \mathcal{H}_o$. We write this step $\langle s \rangle \mapsto (t, m, l)$. The implementation of the compiler is detailed in sections 4.1, 5 and 7, here we just point out that it additionally a variable mapping m and list of links l. The variable map connects unification variables in $\mathcal{H}_o$ with variables in $\mathcal{F}_o$ and is used to "decompile" the assignment, $\langle \sigma, m, l \rangle^{-1} \mapsto \rho$. Links are an accessory piece of information whose description is deferred to section 2.4.

We simulate each run in $\mathcal{F}_o$ with a run in $\mathcal{H}_o$ as follows.

$$\text{hstep}(\mathbb{T}, p, \sigma, \mathbb{L}) \mapsto (\sigma'', \mathbb{L}') \stackrel{def}{=} \sigma\mathbb{T}_{p_l} \simeq_\lambda \sigma\mathbb{T}_{p_r} \mapsto \sigma' \wedge \text{progress}(\mathbb{L}, \sigma \cup \sigma') \mapsto (\mathbb{L}', \sigma'')$$

[1] If the same rule is used multiple times in a run we just consider as many copies as needed of the terms composing the rules, with fresh unification variables each time.

$$\begin{aligned}
&\text{hrun}(\mathbb{P}, \mathcal{N}) \mapsto \rho_{\mathcal{N}} \stackrel{def}{=\!=} \\
&\quad \mathbb{T} \times \mathbb{M} \times \mathbb{L}_0 = \{(t_j, m_j, l_j) | s_j \in \mathbb{P}, \langle s_j \rangle \mapsto (t_j, m_j, l_j)\} \\
&\quad \textstyle\bigwedge_{p=1}^{\mathcal{N}} \text{hstep}(\mathbb{T}, p, \sigma_{p-1}, \mathbb{L}_{p-1}) \mapsto (\sigma_p, \mathbb{L}_p) \\
&\quad \langle \sigma_{\mathcal{N}}, \mathbb{M}, \mathbb{L}_{\mathcal{N}} \rangle^{-1} \mapsto \rho_{\mathcal{N}}
\end{aligned}$$

By analogy with $\mathbb{P}$, we write $\mathbb{T}_{p_l}$ and $\mathbb{T}_{p_r}$ for the two $\mathcal{H}_o$ terms being unified at step p, and we write $\mathbb{T}_p$ for the set $\{\mathbb{T}_{p_l}, \mathbb{T}_{p_r}\}$. hstep is made of two sub-steps: a call to the meta language unification and a check for progress on the set of links, that intuitively will compensate for the weaker equational theory honoured by $\simeq_\lambda$. hrun compiles all terms in $\mathbb{P}$, then executes each step and finally decompiles the solution. We claim:

Proposition 2.1 (Simulation). *$\forall \mathbb{P}, \forall \mathcal{N}$, if $\mathbb{P} \subseteq \mathcal{L}_\lambda$*

$$\text{frun}(\mathbb{P}, \mathcal{N}) \mapsto \rho_{\mathcal{N}} \Leftrightarrow \text{hrun}(\mathbb{P}, \mathcal{N}) \mapsto \rho_{\mathcal{N}}$$

That is, the two executions give the same result. Moreover:

Proposition 2.2 (Simulation fidelity). *In the context of* hrun, *if $\mathbb{P} \subseteq \mathcal{L}_\lambda$ we have that $\forall p \in 1 \dots \mathcal{N}$,*

$$\text{fstep}(\mathbb{P}, p, \rho_{p-1}) \mapsto \rho_p \Leftrightarrow \text{hstep}(\mathbb{T}, p, \sigma_{p-1}, \mathbb{L}_{p-1}) \mapsto (\sigma_p, \mathbb{L}_p)$$

In particular this property guarantees that a *failure* in the $\mathcal{F}_o$ run is matched by a failure in $\mathcal{H}_o$ *at the same step*. We consider this property very important from a practical point of view since it guarantees that the execution traces are strongly related and in turn this enables a user to debug a logic program in $\mathcal{F}_o$ by looking at its execution trace in $\mathcal{H}_o$.

We also claim that hrun handles terms outside $\mathcal{L}_\lambda$ in the following sense:

Proposition 2.3 (Fidelity recovery).

$$\exists \rho, \rho s_1 =_o \rho s_2 \Rightarrow \langle s_i \rangle \mapsto (t_i, m_i, l_i) \Rightarrow t_1 \simeq_\lambda t_2 \mapsto \sigma \qquad (3)$$

$$\sigma_{p-1} \mathbb{T}_p \in \mathcal{L}_\lambda \Rightarrow \qquad (4)$$

$$\exists \rho, \text{fstep}(\mathbb{P}, p, \rho) \mapsto \rho' \Leftrightarrow \text{hstep}(\mathbb{T}, p, \sigma_{p-1}, \mathbb{L}_{p-1}) \mapsto (\sigma_p, \mathbb{L}_p)$$

Property 3 states that two terms for which there is a unifier (given by an oracle and not necessarily a most general one), then the compiler generates two terms that unify in $\mathcal{H}_o$.
Property 4 says that if the two terms involved in a step re-enter $\mathcal{L}_\lambda$, then hstep succeeds. This is a typical example in which the order of the unification problems in a logic-program run does matter. The simplest example is the sequence $F \simeq \lambda x.a$ and $F \cdot a \simeq a$: the second problem is not in $\mathcal{L}_\lambda$ and has two unifiers, namely $\sigma_1 = \{ F \mapsto \lambda x.x \}$ and $\sigma_2 = \{ F \mapsto \lambda x.a \}$. The first problem picks σ_2 making the second problem re-enter $\mathcal{L}_\lambda$. In other words proposition 2.2

2.4 The solution (in a nutshell)

A term s is compiled in a term t where every "problematic" sub term p is replaced by a fresh unification variable h and an accessory *link* that represents a suspended unification problem $h \simeq_\lambda p$. As a result $\simeq_\lambda$ is "well behaved" on t, in the sense that it does not contradict $=_o$ as it would otherwise do on the "problematic" sub-terms. We now define "problematic" and "well behaved" more formally.

Definition 2.4 ($\Diamond\beta_0$). $\Diamond\beta_0$ is the set of terms of the form $X \cdot x_1 \dots x_n$ such that $x_1 \dots x_n$ are distinct names (of bound variables).

An example of term t in $\Diamond\beta_0$ is the application $F \cdot x$. This term is problematic since the application node of its syntax tree cannot be used to justify a unification failure, i.e. by properly instantiating F the term head constructor may become a λ, or a constant or stay an application.

Definition 2.5 ($\Diamond\eta$). $\Diamond\eta$ is the set of terms t such that $\exists \rho, \rho t$ is an eta expansion.

An example of term t in $\Diamond\eta$ is $\lambda x.\lambda y.F \cdot y \cdot x$ since the substitution $\rho = \{F \mapsto \lambda a.\lambda b.f \cdot b \cdot a\}$ makes $\rho t = \lambda x.\lambda y.f \cdot x \cdot y$ that is the eta long form of f. This term is problematic since its leading λ abstraction cannot justify a unification failure against a constant or an application.

Definition 2.6 ($\Diamond\mathcal{L}_\lambda$). $\Diamond\mathcal{L}_\lambda$ is the set of terms of the form $X \cdot t_1 \dots t_n$ such that $t_1 \dots t_n$ are not distinct names.

These terms are problematic for the very same reason terms in $\Diamond\beta_0$ are, but cannot be handled directly by the unification of the meta language, that is only required to handle terms in $\mathcal{L}_\lambda$.

We write $\mathcal{P}(t)$ the set of sub-terms of t, and we write $\mathcal{P}(X) = \bigcup_{t \in X} \mathcal{P}(t)$ when X is a set of terms.

Definition 2.7 (Well behaved set). Given a set of terms $X \subseteq \mathcal{H}_o$,

$$\mathcal{W}(X) \Leftrightarrow \forall t \in \mathcal{P}(X), t \notin (\Diamond\mathcal{L}_\lambda \cup \Diamond\eta \cup \Diamond\beta_0)$$

Proposition 2.8 ($\mathcal{W}$-preservation). $\forall \mathbb{T}, \forall \mathbb{L}, \forall p, \forall \sigma, \forall \sigma'$

$$\begin{aligned}
&\mathcal{W}(\sigma\mathbb{T}) \land \sigma\mathbb{T}_{p_l} \simeq_\lambda \sigma\mathbb{T}_{p_r} \mapsto \sigma' \Rightarrow \mathcal{W}(\sigma'\mathbb{T}) \\
&\mathcal{W}(\sigma\mathbb{T}) \land \text{progress}(\mathbb{L}, \sigma) \mapsto (_, \sigma') \Rightarrow \mathcal{W}(\sigma'\mathbb{T})
\end{aligned}$$

Proposition 2.8 is key to prove propositions 2.1 and 2.2: informally it says that the problematic terms moved on the side by the compiler are not put back by hstep, hence $\simeq_\lambda$ can operate properly. In sections 4.1, 5 and 7 we describe how the compiler recognizes terms in $\Diamond\beta_0$, $\Diamond\eta$ and $\Diamond\mathcal{L}_\lambda$ and how progress takes care of them preserving $\mathcal{W}$ and granting propositions 2.1 and 2.2.

3 GROUND WORK FOR THE COMPILER

Unification variables are identified by a natural number, that represents a memory addresses The memory and its associated operations are described below:

```
kind addr type.
type addr nat -> addr.
typeabbrev (mem A) (list (option A)).

type set? addr -> mem A -> A -> o.
type unset? addr -> mem A -> o.
type assign addr -> mem A -> A -> mem A -> o.
type new mem A -> addr -> mem A -> o.
```

If a memory cell is `none`, then the corresponding unification variable is not set. `assign` sets an unset cell to the given value, while `new` finds the first unused address and sets it to `none`.

Since each occurrence of a $\mathcal{H}_o$ unification variables has a scope, its solution needs to be abstracted over it to enable the instantiation of a single assignment to different scopes. This is expressed by the `inctx` container, and in particular its `abs` binding constructor. On the contrary a solution to a $\mathcal{F}_o$variable is a plain term.

```
typeabbrev fsubst (mem fm).
```

```
kind inctx type -> type.                                    (· ⊢ ·)
type abs (tm -> inctx A) -> inctx A.
type val A -> inctx A.
typeabbrev assignment (inctx tm).
typeabbrev subst (mem assignment).
```

We call fsubst the memory of $\mathcal{F}_o$, while we call subst the one of $\mathcal{H}_o$. The compiler establishes a mapping between variables of the two languages.

```
kind arity type.
type arity nat -> arity.

kind fvariable type.
type fv addr -> fvariable.

kind hvariable type.
type hv addr -> arity -> hvariable.

kind mapping type.
type (<->) fvariable -> hvariable -> mapping.
typeabbrev mmap (list mapping).
```

Each hvariable is stored in the mapping together with its arity so that the code of (*malloc*) below can preserve:

Invariant 1 (Unification variable arity). *Each variable* A *in* $\mathcal{H}_o$ *has a (unique) arity* N *and each occurrence* (uva A L) *is such that* (len L N) *holds*

```
type m-alloc fvariable -> hvariable -> mmap -> mmap ->
  subst -> subst -> o.                                   (malloc)
m-alloc Fv Hv M M S S :- mem M (Fv <-> Hv), !.
m-alloc Fv Hv M [Fv <-> Hv|M] S S1 :- Hv = hv N _, new S N S1.
```

When a single fvariable occurs multiple times with different numbers of arguments the compiler generates multiple mappings for it, on a first approximation, and then makes the mapping bijective by introducing η-link; this detail is discussed in section 6.
As we mentioned in section 2.4 the compiler replaces terms in $\Diamond\eta$, $\Diamond\beta_0$ and $\Diamond\mathcal{L}_\lambda$ with fresh variables linked to the problematic terms. Terms in $\Diamond\beta_0$ do not need a link since $\mathcal{H}_o$ variables faithfully represent the problematic term thanks to their scope.

```
kind baselink type.
type link-eta  tm -> tm -> baselink.
type link-beta tm -> tm -> baselink.
typeabbrev link (inctx baselink).
typeabbrev links (list link).
```

The right hand side of a link, the problematic term, can occur under binders. To accommodate this situation the compiler wraps baselink using the inctx container (see, $\cdot \vdash \cdot$).

Invariant 2 (Link left hand side). *The left hand side of a suspended link is a variable.*

New links are suspended by construction. If the left hand side variable is assigned during a step, then the link is considered for progress and possibly eliminated. This is discussed in section 5 and section 7.

Applying the substitution corresponds to dereferencing a term with respect to the memory. To ease the comparison we split $\mathcal{F}_o$ dereferencing into a fder step and a napp one. The former step replaces references to memory cells that are set with their values, and has a corresponding operation in $\mathcal{H}_o$, namely deref. On the contrary napp has no corresponding operation in $\mathcal{H}_o$, and only ensures that terms of the form «fapp[fapp L1|L2]» are replaced by «fapp L3» where L3 is the concatenation of L1 and L2. The reasons for this asymmetry is that an fapp node with a flexible head is always mapped to a uva (as per sections 4 and 7), preventing nested applications to materialize.

```
type fder fsubst -> fm -> fm -> o.
fder _ (fcon C) (fcon C).
fder S (fapp A) (fapp B) :- map (fder S) A B.
fder S (flam F) (flam G) :-
  pi x\ fder S x x => fder S (F x) (G x).
fder S (fuva N) R :- set? N S T, fder S T R.
fder S (fuva N) (fuva N) :- unset? N S.

type fderef fsubst -> fm -> fm -> o.                    (ρs)
fderef S T T2 :- fder S T T1, napp T1 T2.
```

Applying the substitution in $\mathcal{H}_o$ is very similar, with the caveat that assignments have to be moved to the current scope, i.e. renaming the abs-bound variables with the names in the scope of the unification variable occurrence.

```
type deref subst -> tm -> tm -> o.                      (σt)
deref _ (con C) (con C).
deref S (app A) (app B) :- map (deref S) A B.
deref S (lam F) (lam G) :-
  pi x\ deref S x x => deref S (F x) (G x).
deref S (uva N L) R :- set? N S A,
  move A L T, deref S T R.
deref S (uva N A) (uva N B) :- unset? N S,
  map (deref S) A B.
```

Note that move strongly relies on invariant 1: the length of the arguments of all occurrences of a unification variable and the number of abstractions in its assignment have to match. In turn this grants that move never fails.

```
type move assignment -> list tm -> tm -> o.
move (abs Bo) [H|L] R :- move (Bo H) L R.
move (val A)  [] A.
```

3.1 Notational conventions

When variables x and y can occur in term t we shall write t_{xy} to stress this fact.

We write $\sigma = \{ A_{xy} \mapsto y \}$ for the assignment abs x\abs y\y and $\sigma = \{ A \mapsto \lambda x.\lambda y.y \}$ for lam x\lam y\y .

When detailing examples we write links as equations between two terms under a context. The equality sign is subscripted with kind of baselink. For example $x \vdash A_x =_\beta F_x\ a$ corresponds to:

```
abs x\ val (link-beta (uva A [x]) (app[uva F [x],con "a"]))
```

notation for problem compilation

4 BASIC SIMULATION OF $\mathcal{F}_o$ IN $\mathcal{H}_o$

In this section we describe a basic compilation scheme that we refine later, in the following sections. This scheme is sufficient to implement a hstep that respects β-conversion for terms in $\mathcal{L}_\lambda$. The extension to $\eta\beta$-conversion is described in section 5 and the support for terms outside $\mathcal{L}_\lambda$ in section 7.

4.1 Compilation

E:manca beta normal in entrata

The main task of the compiler is to recognize $\mathcal{F}_o$ variables standing for functions and map them to higher order variables in $\mathcal{H}_o$. In order to bring back the substitution from $\mathcal{H}_o$ to $\mathcal{F}_o$ the compiler builds a "memory map" connecting the the kind of variables using routine (*malloc*).

The signature of the comp predicate below allows for the generation of links (suspended unification problems) that play no role in this section but play a major role in section 5 and section 7. With respect to section 2 the signature also allows for updates to the substitution.

```
type comp fm -> tm -> mmap -> mmap -> links -> links ->
  subst -> subst -> o.
comp (fcon C) (con C) M M L L S S.
comp (flam F) (lam F1) M1 M2 L1 L2 S1 S2 :-                (cλ)
  comp-lam F F1 M1 M2 L1 L2 S1 S2.
comp (fuva A) (uva B []) M1 M2 L L S1 S2 :-
  m-alloc (fv A) (hv B (arity z)) M1 M2 S1 S2.
comp (fapp A) (app A1) M1 M2 L1 L2 S1 S2 :-                (c@)
  fold6 comp A A1 M1 M2 L1 L2 S1 S2.
```

The code above uses that possibility in order to allocate space for the variables, i.e. sets their memory address to none (a details not worth mentioning in the previous sections).

```
type comp-lam (fm -> fm) -> (tm -> tm) ->
  mmap -> mmap -> links -> links -> subst -> subst -> o.
comp-lam F G M1 M2 L1 L3 S1 S2 :-
  pi x y\ (pi M L S\ comp x y M M L L S S) =>
    comp (F x) (G y) M1 M2 L1 (L2 y) S1 S2,
  close-links L2 L3.
```

In the code above the syntax `pi x y\..` is syntactic sugar for iterated pi abstraction, as in `pi x\ pi y\...`

The auxiliary function close-links tests if the bound variable v really occurs in the link. If it is the case the link is wrapped into an additional abs node binding v. In this way links generated deep inside the compiled terms can be moved outside their original context of binders.

```
type close-links (tm -> links) -> links -> o.
close-links (v\[X  |L v]) [X|R] :- !, close-links L R.
close-links (v\[X v|L v]) [abs X|R] :- close-links L R.
close-links (_\[]) [].
```

Note that we could remove the first rule, whose solve purpose is to make links more readable by pruning unused context entries.

4.1.1 Compilation of terms in $\diamond\beta_0$. The following rule is inserted just before rule ($c_@$).

```
comp (fapp [fuva A|Ag]) (uva B Ag1) M1 M2 L L S1 S2 :-
  pattern-fragment Ag, !,
    fold6 comp Ag Ag1 M1 M1 L L S1 S1,
    len Ag Arity,
    m-alloc (fv A) (hv B (arity Arity)) M1 M2 S1 S2.
```

Note that compiling Ag cannot create new mappings nor links, since Ag is made of bound variables and the hypothetical rule loaded by comp-lam (see below) grants this property. Also note that this rule generates no links.

The only detail worth discussing is the fact that the procedure updates a substitution, rather than just crafting one as presented in section 2. The reason is that the algorithm folds over a term, updating a substitution while it traverses it.

E:explain better

4.2 Execution

A step in $\mathcal{H}_o$ consists in unifying two terms and reconsidering all links for progress. If any of the two tasks fail we say that the entire step fails, and it is at this granularity that we can relate steps in the two languages.

```
type hstep tm -> tm -> links -> links -> subst -> subst -> o.
hstep T1 T2 L1 L2 S1 S3 :-
  (T1 ≃λ T2) S1 S2,
  progress L1 L2 S2 S3.
```

Note tha the infix notation `((A ≃λ B) C D)` is syntactic sugar for `((≃λ) A B C D)`.

Reconsidering links is a fixpoint, since the progress of a link can update the substitution and in turn enable another link to progress.

```
type progress links -> links -> subst -> subst -> o.
progress L L2 S1 S3 :-
  progress1 L L1 S1 S2,
  occur-check-links L1,
  if (L = L1, S1 = S2)
     (L2 = L1, S3 = S1)
     (progress L1 L2 S2 S3).
```

In the base compilation scheme progress1 is the identity on both the links and the substitution, so the fixpoint trivially terminates. Sections 5 and 7 add rules to progress1 and justify why the don't hinder termination. For brevity we omit the code that applies the substitution S1 to all terms in $\mathbb{L}$.

Since compilation moves problematic terms out of the sigh of $\simeq_\lambda$, that procedure can only perform a partial occur check. For example the unification problem $X \simeq_\lambda f\ Y$ cannot generate a cyclic substitution alone, but should be disallowed if a $\mathbb{L}$ contains a link like $\vdash Y =_\eta \lambda z.X_z$: We don't know yet if Y will feature a lambda in head position, but we surely know it contains X, hence $f\ Y$ and that fails the occur check. The procedure occur-check-links is in charge of ensuring that each link does not represent a (suspended) unification problem doomed to fail because of occur check. This check is needed in order to guarantee proposition 2.2 (simulation fidelity).

4.3 Substitution decompilation

Decompiling the substitution requires to first force the progress of links and then allocating new unassigned variables in the substitution for $\mathcal{F}_o$ and finally decompiling all assignments. Note that invariant 2 and the occur check allows us to update the subst.

```
type decompile mmap -> links -> subst ->
  fsubst -> fsubst -> o.
```

```
decompile M1 L S F1 F3 :-
  commit-links L S S1,
  complete-mapping S1 S1 M1 M2 F1 F2,
  decompm M2 M2 S1 F2 F3.
```

E:What is commit-links and complete-mapping?

Decompiling an assignment requires to turn abstractions into lambdas. For aesthetic purposes we also eta-contract the result (not needed since $\mathcal{F}_o$ equality can do that)

```
type decompm mmap -> mmap -> subst -> fsubst -> fsubst -> o.
decompm _ [] _ F F.
decompm M [fv V <-> hv H _|MS] S F1 F3 :- set? H S A,
  deref-assmt S A A1,
  abs->lam A1 T, decomp M T T1,
  eta-contract T1 T2,
  assign V F1 T2 F2,
  decompm M MS S F2 F3.
decompm M [_ <-> hv H _|MS] S F1 F2 :- unset? H S,
  decompm M MS S F1 F2.
```

Finally decompiling a term is trivial, now that we have an extended mapping containing all unassigned variables $\simeq_\lambda$ may have introduced.

```
type decomp mmap -> tm -> fm -> o.
decomp _ (con C)  (fcon C).
decomp M (app A) (fapp B) :- map (decomp M) A B.
decomp M (lam F) (flam G) :-
  pi x y\ (pi M\ decomp M x y) => decomp M (F x) (G y).
decomp M (uva Hv Ag) R :-
  mem M (fv Fv <-> hv Hv _),
  map (decomp M) Ag Bg,
  beta (fuva Fv) Bg R.
```

Note that we use beta to build fapp nodes when needed (if Ag is empty no fapp node should appear).

Invariant 3. *TODO: dire che il mapping è bijective*

4.4 Definition of $\simeq_o$ and its properties

```
type (≃o) fm -> fm -> fsubst -> o.
(A ≃o B) F :-
  comp A A' [] M1 [] [] [] S1,
  comp B B' M1 M2 [] [] S1 S2,
  hstep A' B' [] [] S2 S3,
  decompm M2 M2 S3 [] F.
```

The code given so far applies to terms in $\beta\eta$-normal form where unification variables in $\mathcal{F}_o$ can occur non linearly but always with the same number of arguments, and where their arguments are distinct names (as per $\mathcal{L}_\lambda$).

Lemma 4.1 (Compilation round trip). *If* `comp S T [] M [] _ [] _` *then* `decomp M T S`

Proof sketch. trivial, since the terms are beta normal beta just builds an app. □

D:Reformulate?

Lemma 4.2. *Properties* (1) *and* (2) *hold for the implementation of* $\simeq_o$ *above*

Proof sketch. In this setting $=_\lambda$ is as strong as $=_o$ on ground terms. What we have to show is that whenever two different $\mathcal{F}_o$ terms can be made equal by a substitution ρ (plus the β_l and β_r if needed) we can find this ρ by finding a σ via $\simeq_\lambda$ on the corresponding $\mathcal{H}_o$ terms and by decompiling it. If we look at the $\mathcal{F}_o$ terms, the are two interesting cases:

- `fuva X` $\simeq_o$ s. In this case after `comp` we have $Y \simeq_\lambda t$ that succeeds with $\sigma = \{Y \mapsto t\}$ and σ is decompiled to $\rho = \{Y \mapsto s\}$.
- `fapp[fuva X|L]` $\simeq_o$ s. In this case we have $Y_{\vec{x}} \simeq_\lambda t$ that succeeds with $\sigma = \{\vec{y} \vdash Y \mapsto t[\vec{x}/\vec{y}]\}$ that in turn is decompiled to $\rho = \{Y \mapsto \lambda\vec{y}.s[\vec{x}/\vec{y}]\}$. Thanks to β_l $(\lambda\vec{y}.s[\vec{x}/\vec{y}])\,\vec{x} =_o s$.

Since the mapping is a bijection occur check in $\mathcal{H}_o$ corresponds to occur check in $\mathcal{F}_o$. □

Lemma 4.3. *Proposition 2.1 (Simulation) and proposition 2.2 (Simulation fidelity) hold*

Proof sketch. Since `progress1` is trivial fstep and hstep are the same, that is in this context where input terms are $\beta\eta$-normal and we disregard η-equivalence $\simeq_\lambda$ is equivalent to $\simeq_o$. □

4.5 Limitations of by this basic scheme

The basic compilation scheme is not about to deal wit the following problem:

$$\mathbb{P} = \{\ \lambda xy.X\cdot y\cdot x \simeq_o \lambda xy.x \quad \lambda x.f\cdot(X\cdot x)\cdot x \simeq_o Y\ \}$$

Note that here X is used with different arities, moreover in the second problem the left hand side happens to be an eta expansion (of $f(\lambda y.y)$) only after we discover (at run time) that $X = \lambda x\lambda y.y$ (i.e. that X discards the x argument). Both problems are addressed in the next two sections.

5 HANDLING OF $\Diamond\eta$

η-reduction is an equivalence relation where a term of the form $\lambda x.t\cdot x$ can be converted to t any time x does not occur as a free variable in t. We call t the η-contraction of $\lambda x.t\cdot x$.

Following the compilation scheme of section 4.1 the unification problem $\mathbb{P}$ is compiled as follows:

$$\begin{aligned}\mathbb{P} &= \{\ \lambda x.X\cdot x \simeq_o f\ \}\\ \mathbb{T} &= \{\ \lambda x.A_x \simeq_\lambda f\ \}\\ \mathbb{M} &= \{\ X \mapsto A^1\ \}\end{aligned}$$

While $\lambda x.X\cdot x \simeq_o f$ does admit the solution $\rho = \{\ X \mapsto f\ \}$, the corresponding problem in $\mathbb{T}$ does not: `lam x\ uva A [x]` and `con"f"` start with different, rigid, term constructors hence $\simeq_\lambda$ fails.

In order to guarantee proposition 2.1 we detect lambdas that can disappear by eta contraction (section 5.1) and we modify the compiled terms by putting fresh unification variables in their place: the problematic term is moved from $\mathbb{T}$ to $\mathbb{L}$ (section 5.2). The compilation of the problem $\mathbb{P}$ above is refined to:

$$\begin{aligned}\mathbb{P} &= \{\ \lambda x.X\cdot x \simeq_o f\ \}\\ \mathbb{T} &= \{\ A \simeq_\lambda f\ \}\\ \mathbb{M} &= \{\ X \mapsto B^1\ \}\\ \mathbb{L} &= \{\ \vdash A =_\eta \lambda x.B_x\ \}\end{aligned}$$

As per invariant 2 the term on the left is a variable, and its right counterpart is the term in $\Diamond\eta$. That term has the following property:

Invariant 4 (η-`link` rhs). *The* rhs *of any* η-`link` *has the shape* $\lambda x.t$ *and* t *is not a lambda.*

η-`link` are kept in the link store $\mathbb{L}$ during execution and activated when some conditions hold on lhs or rhs. Link activation is implemented by extending the `progress1` predicate (defined in section 4.2).

5.1 Detection of $\Diamond\eta$

When compiling a term t we need to determine if any subterm $s \in \mathcal{P}(t)$ that is of the form $\lambda x.r$, where x occurs in r, can be a η-expansion, i.e. if there exists a substitution ρ such that $\rho(\lambda x.r) =_o s$. The detection of lambda abstractions that can "disappear" is not as trivial as it may seems, here a few examples:

$$\begin{array}{lll}
\lambda x.f \cdot (A \cdot x) & \in \Diamond\eta & \rho = \{ A \mapsto \lambda x.x \} \\
\lambda x.f \cdot (A \cdot x) \cdot x & \in \Diamond\eta & \rho = \{ A \mapsto \lambda x.a \} \\
\lambda x.f \cdot x \cdot (A \cdot x) & \notin \Diamond\eta & \\
\lambda x.\lambda y.f \cdot (A \cdot x) \cdot (B \cdot y \cdot x) & \in \Diamond\eta & \rho = \{ A \mapsto \lambda x.x,\ B \mapsto \lambda y.\lambda x.y \}
\end{array}$$

The first two examples are easy, and show how a unification variable can expose or erase a variable in their scope and turn the resulting term in an η-expansion or not.
The third example shows that when a variable occurs outside the scope of a unification variable it cannot be erased and can hence prevent a term from being an η-expansion.
The last example shows the recursive nature of the check we need to implement. The term starts with a spine of two lambdas hence the whole term is in $\Diamond\eta$ iff the inner term $\lambda y.f \cdot (A \cdot x) \cdot (B \cdot y \cdot x)$ is in $\Diamond\eta$ itself. If it is, it could η-contract to $f \cdot (A \cdot x)$ making $\lambda x.f \cdot (A \cdot x)$ a potential η-expansion.
We can now define more formally how $\Diamond\eta$ terms are detected together with its auxiliary functions:

Definition 5.1 (may-contract-to). A β-normal term s *may-contract-to* a name x if there exists a substitution ρ such that $\rho s =_o x$.

Lemma 5.2. *A β-normal term $s = \lambda x_1 \ldots x_n.t$* may-contract-to x *only if one of the following three conditions holds:*

(1) $n = 0$ and $t = x$;
(2) t is the application of x to a list of terms l and each l_i may-contract-to x_i *(e.g. $\lambda x_1 \ldots x_n.x \cdot x_1 \ldots x_n =_o x$) ;*
(3) t is a unification variable with scope W, and for any $v \in \{x, x_1 \ldots x_n\}$, there exists a $w_i \in W$, such that w_i may-contract-to v *(if $n = 0$ this is equivalent to $x \in W$).*

Proof sketch. Since our terms are in β-normal form there is only one rule that can play a role (namely η_l), hence if the term s is not exactly x (case 1) it can only be an η-expansion of x, or a unification variable that can be assigned to x, or a combination of both. If s begins with a lambda, then the lambda can only disappear by η contraction. In that case the term t is under the spine of binders $x_1 \ldots x_n$, t can either be x applied to terms that can *may-contract-to* these variables (case 2), or a unification variable that can be assigned to that application (case 3). ◻

Definition 5.3 (occurs-rigidly). A name x *occurs-rigidly* in a β-normal term t, if $\forall \rho, x \in \mathcal{P}(\rho t)$

In other words x *occurs-rigidly* in t if it occurs in t outside of the scope of a unification variable X, otherwise an instantiation of X can make x disappears from t. Moreover, note that η-contracting t cannot make x disappear, since x is not a locally bound variable inside t.

We can now derive the implementation for $\Diamond\eta$ detection:

Definition 5.4 (maybe-eta). Given a β-normal term $s = \lambda x_1 \ldots x_n.t$, *maybe-eta* s holds if any of the following holds:

(1) t is a constant or a name applied to the arguments $l_1 \ldots l_m$ such that $m \geq n$ and for every i such that $m - n < i \leq m$ the term l_i *may-contract-to* x_i, and no x_i *occurs-rigidly* in $l_1 \ldots l_{m-n}$;
(2) t is a unification variable with scope W and for each x_i there exists a $w_j \in W$ such that w_j *may-contract-to* x_i.

Lemma 5.5 ($\Diamond\eta$ detection). *If t is a β-normal term and* maybe-eta t *holds, then $t \in \Diamond\eta$.*

Proof sketch. Follows from definition 5.3 and lemma 5.2 ◻

Remark that the converse of lemma 5.5 does not hold: there exists a term t satisfying the criteria (1) of definition 5.4 that is not in $\Diamond\eta$, i.e. there exists no substitution ρ such that ρt is an η-expansion. A simple counter example is $\lambda x.f \cdot (A \cdot x) \cdot (A \cdot x)$ since x does not *occur-rigidly* in the first argument of f, and the second argument of f *may-contract-to* x. In other words $A \cdot x$ may either use or discard x, but our analysis does not take into account that *the same term* cannot have two contrasting behaviors.

As we will see in the rest of this section this is not a problem since it does not break proposition 2.1 nor proposition 2.2.

5.2 Compilation and decompilation

Compilation. The following rule is inserted just before rule (c_λ) from the code in section 4.1.

```
comp (flam F) (uva A Scope) M1 M2 L1 L3 S1 S3 :-
  maybe-eta (flam F) [], !,
    alloc S1 A S2,
    comp-lam F F1 M1 M2 L1 L2 S2 S3,
    get-scope (lam F1) Scope,
    L3 = [val (link-eta (uva A Scope) (lam F1)) | L2].
```

The rule triggers when the input term `flam F` is in $\Diamond\eta$. It compiles `flam F` to `lam F1` but puts the fresh variable `A` in its place. This variable sees all the names free in `lam F1`. The critical part of this rule is the creation of the η-`link`, which relates the variable `A` with `lam F1`. This link clearly validates invariant 2.

Corollary 5.6. *The* rhs *of any* η-`link` *has exactly one lambda abstraction, hence the rule above respects invariant 4.*

Proof sketch. By contradiction, suppose that the rule above is triggered and that the rhs of the link is $\lambda x.\lambda y.t_{xy}$. If *maybe-eta* $\lambda y.t_{xy}$ holds the recursive call to `comp` (made by `comp-lam`) must have put a fresh variable in its place, so this case is impossible. Otherwise, if *maybe-eta* $\lambda y.t_{xy}$ does not hold, also *maybe-eta* $\lambda x.\lambda y.t_{xy}$ does not hold, contradicting the assumption that the rule triggered. ◻

Decompilation. Decompilation of the remaining η-`link` (i.e. the η-`link` that have been activated) is performed by iterating over them and unifying lhs and rhs. Note that this unification never fails, since lhs is a flexible term not appearing in any other η-`link` (by definition 5.9).

5.3 Progress

η-`link` are meant to delay the unification of "problematic" terms until we know for sure if the term has to be η-contracted or not.

*Definition 5.7 (*progress-η-left*).* A link $\Gamma \vdash X =_\eta T$ is removed from $\mathbb{L}$ when X becomes rigid. Let $y \in \Gamma$, there are two cases:

(1) if $X = a$ or $X = y$ or $X = f \cdot a_1 \dots a_n$ we unify the η-expansion of X with T, that is we run $\lambda x.X \cdot x \simeq_\lambda T$
(2) if $X = \lambda x.t$ we run $X \simeq_\lambda T$.

*Definition 5.8 (*progress-η-right*).* A link $\Gamma \vdash X =_\eta T$ is removed from $\mathbb{L}$ when either 1) *maybe-eta* T does not hold (anymore) or 2) by η-contracting T to T', T' is a term not starting with the `lam` constructor. In the first case, X is unified with T and in the second one, X is unified with T' (under the context Γ).

There is a third case in which a link is removed from $\mathbb{L}$, namely when the lhs is assigned to a variable that is the lhs of another η-`link`.

*Definition 5.9 (*progress-η-deduplicate*).* A link $\Gamma \vdash X_{\vec{s}} =_\eta T$ is removed from $\mathbb{L}$ when another link $\Delta \vdash X_{\vec{r}} =_\eta T'$ is in $\mathbb{L}$. By invariant 1 the length of $\vec{s}$ and $\vec{r}$ is the same hence we can move the term T' from Δ to Γ by renaming its bound variables, i.e. $T'' = T'[\vec{r}/\vec{s}]$. We then run $T \simeq_\lambda T''$ (under the context Γ).

Lemma 5.10. *Let $\lambda x.t$ the* rhs *of a η-`link`, then $\mathcal{W}t$.*

Proof sketch. By construction, every "problematic" term in $\mathcal{F}_o$ is replaced with a variable in the corresponding $\mathcal{H}_o$ term. Therefore, t is $\mathcal{W}$. ◻

Lemma 5.11. *Given a η-`link` l, the unification done by* progress-η-left *is between terms in $\mathcal{W}$*

Proof sketch. Let σ be the substitution, which is $\mathcal{W}(\sigma)$ (by proposition 2.8). lhs $\in \sigma$, therefore $\mathcal{W}$(lhs). By *progress-η-left*, if 1) lhs is a name, a constant or an application, then, $\lambda x.$lhs $\cdot x$ is unified with rhs. By invariant 4 and lemma 5.10, rhs $= \lambda x.t$ and $\mathcal{W}(t)$. Otherwise, 2) lhs has `lam` as functor. In both cases, unification is performed between terms in $\mathcal{W}$. ◻

Lemma 5.12. *Given a η-`link` l, the unification done by* progress-η-right *is between terms in $\mathcal{W}$.*

Proof sketch. lhs is variable, and, by definition 5.8, rhs is either no more a $\Diamond\eta$, i.e. rhs is not a η-expansion and, so, $\mathcal{W}$(rhs), otherwise, rhs can reduce to a term which cannot be a η-expansion, and, so, $\mathcal{W}$(rhs). In both cases, the unification between rhs and lhs is done between terms that are in $\mathcal{W}$. ◻

Lemma 5.13. *Given a η-`link` l, the unification done by* progress-η-deduplicate *is between terms in $\mathcal{W}$.*

Proof. The unification is done between the rhs of two η-`link`. Both rhs has the shape $\lambda x.t$, and by lemma 5.10, $\mathcal{W}(t)$. Therefore, the unification is done between well-behaved terms. ◻

Lemma 5.14. *The introduction of η-`link` guarantees proposition 2.8 ($\mathcal{W}$-preservation)*

Proof sketch. By lemmas 5.11 to 5.13, every unification performed by the activation of a η-`link` is done between terms in $\mathcal{W}$, therefore, the substitution remains $\mathcal{W}$. ◻

Lemma 5.15. `progress` *terminates.*

Proof sketch. Rules definitions 5.7 and 5.8 and definition 5.9 remove one link from $\mathbb{L}$, hence they cannot be applied indefinitely. Moreover each rule only relies on terminating operations such as $\simeq_\lambda$, η-contraction, η-expansion, relocation (a recursive copy of a finite term). ◻

Lemma 5.16 (Fidelity with η-`link`). *The introduction of η-`link` guarantees proposition 2.2 (Simulation fidelity)*

Proof sketch. *progress-η-left* and *progress-η-deduplicate* activate a η-`link` when, in the original unification problem, a $\Diamond\eta$ term is unified with respectively a well-behaved term or another $\Diamond\eta$ term. In both cases, the links trigger a unification which succeeds iff the same unification in $\mathcal{F}_o$ succeeds, guaranteeing proposition 2.2. *progress-η-right* never fails, in fact, this progression refines a variable to a rigid term and plays no role in proposition 2.2. ◻

Example of progress-η-left. The example at the beginning of section 5, once $\sigma = \{ A \mapsto f \}$, triggers *progress-$\eta$-left* since the link becomes $\vdash f =_\eta \lambda x.B_x$ and the lhs is a constant. In turn the rule runs $\lambda x.f \cdot x \simeq_\lambda \lambda x.B_x$, resulting in $\sigma = \{ A \mapsto f \,;\, B_x \mapsto f \}$. Decompilation the generates $\rho = \{ X \mapsto f \}$, since X is mapped to B and f is the η-contracted version of $\lambda x.f \cdot x$.

Example of progress-η-deduplicate. A very basic example of η-`link` deduplication, is given below:

$$\begin{aligned}
\mathbb{P} &= \{\ \lambda x.(X \cdot x) \ \simeq_o\ \lambda x.(Y \cdot x)\ \} \\
\mathbb{T} &= \{\ \qquad A \ \simeq_\lambda\ C \qquad \} \\
\mathbb{M} &= \{\ \ X \mapsto B^1 \quad\ Y \mapsto D^1\ \ \} \\
\mathbb{L} &= \{\ \vdash A =_\eta \lambda x.B_x \quad \vdash C =_\eta \lambda x.D_x\ \}
\end{aligned}$$

The result of $A \simeq_\lambda C$ is that the two η-`link` share the same lhs. By unifying the two rhs we get $\sigma = \{A \mapsto C, B \mapsto D\,\}$. In turn, given the map $\mathbb{M}$, this second assignment is decompiled to $\rho = \{ X \mapsto Y \}$ as expected.

We delay at the end of next section an example of η-`link` progression due to *progress-η-right*

6 ENFORCING INVARIANT 1

We report here the problem given in section 4.5 where X is used with two different arities and the output of the compilation does not respect invariant 3 (merging the two mappings for s would break invariant 1). In this section we explain how to replace the duplicate mapping with some η-`link` in order to restore the invariants.

$$\begin{array}{l} \mathbb{P} = \{\ \lambda x.\lambda y.(X \cdot y \cdot x) \simeq_o \lambda x.\lambda y.x \quad \lambda x.(f \cdot (X \cdot x) \cdot x) \simeq_o Y\ \} \\ \mathbb{T} = \{\ A \simeq_\lambda \lambda x.\lambda y.x \quad D \simeq_\lambda F\ \} \\ \mathbb{M} = \{\ X \mapsto E^1 \quad Y \mapsto F^0 \quad X \mapsto C^2\ \} \\ \mathbb{L} = \left\{ \begin{array}{ll} \vdash D =_\eta \lambda x.(f \cdot E_x \cdot x) & \vdash A =_\eta \lambda x.B_x \\ x \vdash B_x =_\eta \lambda y.C_{yx} & \end{array} \right\} \end{array}$$

We see that the `maybe-eta` as identified $\lambda xy.X \cdot y \cdot x$ and $\lambda x.f \cdot (X \cdot x) \cdot x$ and the compiler has replaced them with A and D respectively. However, the mapping $\mathbb{M}$ breaks invariant 3: the $\mathcal{F}_o$ variable X is mapped to two different $\mathcal{H}_o$ variables. To address this problem we adjust the compiler's output with a `map-deduplication` procedure.

*Definition 6.1 (*align-arity*).* Given two mappings $m_1 : X \mapsto A^m$ and $m_2 : X \mapsto C^n$ where $m < n$ and $d = n - m$, *align-arity* m_1 m_2 generates the following d links, one for each i such that $0 \le i < d$,

$$x_0 \dots x_{m+i} \vdash B^i_{x_0 \dots x_{m+i}} =_\eta \lambda x_{m+i+1}.B^{i+1}_{x_0 \dots x_{m+i+1}}$$

where B^i is a fresh variable of arity $m + i$, and $B^0 = A$ as well as $B^d = C$.

The intuition is that we η-expand the occurrence of the variable with lower arity to match the higher arity. Since each η-`link` can add exactly one lambda, we need as many links as the difference between the two arities.

*Definition 6.2 (*map-deduplication*).* Forall mappings $m_1, m_2 \in \mathbb{M}$ such that $m_1 : X \mapsto A^m$ and $m_2 : X \mapsto C^n$ and $m < n$ we remove m_1 from $\mathbb{M}$ and add to $\mathbb{L}$ the result of *align-arity* m_1 m_2.

If we look back the example give at the beginning of this section, we can deduplicate $X \mapsto E^1, X \mapsto C^2$ by removing the first mapping and adding the auxiliary η-`link`: $x \vdash E_x =_\eta \lambda y.C_{xy}$. After deduplication the compiler output is as follows:

$$\begin{array}{l} \mathbb{P} = \{\ \lambda x.\lambda y.(X \cdot y \cdot x) \simeq_o \lambda x.\lambda y.x \quad \lambda x.(f \cdot (X \cdot x) \cdot x) \simeq_o Y\ \} \\ \mathbb{T} = \{\ A \simeq_\lambda \lambda x.\lambda y.x \quad D \simeq_\lambda F\ \} \\ \mathbb{M} = \{\ Y \mapsto F^0 \quad X \mapsto C^2\ \} \\ \mathbb{L} = \left\{ \begin{array}{ll} x \vdash E_x =_\eta \lambda y.C_{xy} & \vdash D =_\eta \lambda x.(f \cdot E_x \cdot x) \\ \vdash A =_\eta \lambda x.B_x & x \vdash B_x =_\eta \lambda y.C_{yx} \end{array} \right\} \end{array}$$

In this example, $\mathbb{T}_1$ assigns A which triggers $\mathbb{L}_3$ and then $\mathbb{L}_4$ by definition 5.7. C_{yx} is therefore assigned to x (the second variable of its scope). We can finally see the *progress-η-right* of $\mathbb{L}_1$: its rhs is now $\lambda y.y$ (C_{xy} gives y). Since it is no more in $\Diamond\eta$, $\lambda y.y$ is unified with E_x. Moreover, $\mathbb{L}_2$ is also triggered due to definition 5.8: $\lambda x.(f \cdot (\lambda y.y) \cdot x)$ is η-reducible to $f \cdot (\lambda y.y)$ which is a term not starting with the `lam` constructor.

7 HANDLING OF $\Diamond\mathcal{L}_\lambda$

In general, unification between $\Diamond\mathcal{L}_\lambda$ terms admits more then one solution and committing one of them in the substitution does not guarantee **??**. For instance, $X \cdot a \simeq_o a$ admits two different substitutions: $\rho_1 = \{X \mapsto \lambda x.x\}$ and $\rho_2 = \{X \mapsto \lambda\_.a\}$. Prefer one over the other may break future unifications.

It is the case, however, that, given a list of unification problems, $\mathbb{P}_1 \dots \mathbb{P}_n$ with $\mathbb{P}_n$ in $\Diamond\mathcal{L}_\lambda$, the resolution of $\bigwedge_{i=0}^{n-1} \mathbb{P}_i$ gives a partial substitution ρ, such that $\rho\mathbb{P}_n$ falls again in $\mathcal{L}_\lambda$.

$$\begin{array}{l} \mathbb{P} = \{\ X \simeq_o \lambda x.Y \quad (X \cdot a) \simeq_o a\ \} \\ \mathbb{T} = \{\ A \simeq_\lambda \lambda x.B \quad (A \cdot a) \simeq_\lambda a\ \} \\ \mathbb{M} = \{\ Y \mapsto B^0 \quad X \mapsto A^0\ \} \end{array}$$

In the example above, we see that $\mathbb{P}_1$ instantiates X so that $\mathbb{P}_2$ can be solved in $\mathcal{L}_\lambda$. On the other hand, we see that, $\simeq_\lambda$ can't solve the compiled problems $\mathbb{T}$. In fact, the resolution of $\mathbb{T}_1$ gives the substitution $\sigma = \{A \mapsto \lambda x.B\}$, but the dereferencing of $\mathbb{T}_2$ gives the non-unifiable problem $(\lambda x.B) \cdot a \not\simeq_\lambda a$.

To address this unification problem, term compilation should capture the terms in $\Diamond\mathcal{L}_\lambda$ and replace them with fresh variables. This replacement should produce links that we call β-`link`.

β-`link` guarantees invariant 2 and the term on the rhs has the following property:

Invariant 5 (β-`link` rhs). *The* rhs *of any* β-`link` *has the shape* $X_{s_1 \dots s_n} \cdot t_1 \dots t_m$ *such that* X *is a unification variable with scope* $s_1 \dots s_n$ *and* $t_1 \dots t_m$ *is a list of terms. This is equivalent to* `app[uva X S | L]`, *where* `S` $= s_1 \dots s_n$ *and* `L` $= t_1 \dots t_m$.

7.1 Compilation and decompilation

Detection of $\Diamond\mathcal{L}_\lambda$ is quite simple to implement in the compiler, since it is sufficient to detect applications with flexible head and argument that are not in $\mathcal{L}_\lambda$. The following rule for $\Diamond\mathcal{L}_\lambda$ compilation is inserted just before rule $(c_@)$.

```
comp (fapp [fuva A|Ag]) (uva B Scope) M1 M3 L1 L3 S1 S4 :- !,
  pattern-fragment-prefix Ag Pf Extra,
  len Pf Arity,
  alloc S1 B S2,
  m-alloc (fv A) (hv C (arity Arity)) M1 M2 S2 S3,
  fold6 comp Pf    Pf1    M2 M2 L1 L1 S3 S3,
  fold6 comp Extra Extra1 M2 M3 L1 L2 S3 S4,
  Beta = app [uva C Pf1 | Extra1],
  get-scope Beta Scope,
  L3 = [val (link-beta (uva B Scope) Beta) | L2].
```

The list `Ag` is split into the list `Pf` and `Extra` such that `append Pf Extra Ag` and `Pf` is the largest prefix of `Ag` such that `Pf` is in $\mathcal{L}_\lambda$. The rhs of the β-`link` is the application of a fresh variable `C` having in scope all the free variables appearing in the compiled version of `Pf` and `Extra`. The variable `B`, returned has the compiled term, is a fresh variable having in scope all the free variables occurring in `Pf1` and `Extra1`

Invariant 6. *The* rhs *of a* β-`link` *has the shape* $X_{s_1 \dots s_n} \cdot t_1 \dots t_m$.

Corollary 7.1. *Let* $X_{s_1 \dots s_n} \cdot t_1 \dots t_m$ *be the* rhs *of a* β-`link`, *then* $m > 0$.

Proof sketch. Assume we have a β-`link`, by contradiction, if $m = 0$, then the original $\mathcal{F}_o$ term has the shape `fapp[fuva M | Ag]` where `Ag` is a list of distinct names (i.e. the list `Extra` is empty). This case is however captured by rule (c_λ) (from section 4.1) and no β-`link` is produced which contradicts our initial assumption. □

Corollary 7.2. *Let* $X_{s_1 \dots s_n} \cdot t_1 \dots t_m$ *be the* rhs *of a* β-`link`, *then* t_1 *either appears in* $s_1 \dots s_n$ *or it is not a name.*

Proof sketch. By construction, the lists $s_1 \dots s_n$ and $t_1 \dots t_m$ are built by splitting the list `Ag` from the original term `fapp [fuva A|Ag]`. $s_1 \dots s_n$ is the longest prefix of the compiled terms in `Ag` which is in $\mathcal{L}_\lambda$. Therefore, by definition of $\mathcal{L}_\lambda$, t_1 must appear in $s_1 \dots s_n$, otherwise $s_1 \dots s_n$ is not the longest prefix in $\mathcal{L}_\lambda$, or it is a term with a constructor of `tm` as functor. □

E:Dire che maybe eta fa il detect anche su termini che non sono il llambda, oppure dirlo in section of maybeeta + dare un esempio?

Decompilation. During `progress`, as claimed in invariant 5, the decompilation can only have β-`link` with not instantiated lhs. In this case, lhs is unified with rhs.

D:not really sure of this, we can have $F\ a = \lambda x.Gx$. In this case when do we fail: for sure in decompile. But to respect fidelity, we should fail immediately: we have a β-`link` and a η-`link` with same lhs

7.2 Progress

The activation of a β-`link` is performed when its rhs falls under $\mathcal{L}_\lambda$ under a given substitution.

Definition 7.3 (progress-beta-$\mathcal{L}_\lambda$)*.* Given a substitution σ and a β-`link` $\Gamma \vdash T =_\beta X_{s_1 \ldots s_n}\, t_1 \ldots t_m$ such that σt_1 is a name, say t, and $t \notin s_1 \ldots s_n$. If $m = 0$, then the β-`link` is removed and lhs is unified with $X_{s_1 \ldots s_n}$. If $m > 0$, then the β-`link` is replaced by a refined version $\Gamma \vdash T =_\beta Y_{s_1 \ldots s_n, t}\, t_2 \ldots t_m$ with reduced list of arguments and Y being a fresh variable. Moreover, the new link $\Gamma \vdash X_{s_1 \ldots s_n} =_\eta \lambda x.Y_{s_1 \ldots s_n, x}$ is added to $\mathbb{L}$.

D:L'ho riformulato

Definition 7.4 (progress-beta-rigid-rhs)*.* A link $\Gamma \vdash X =_\beta X_{s_1 \ldots s_n}\, t_1 \ldots t_m$ is removed from $\mathbb{L}$ if $X_{s_1 \ldots s_n}$ is instantiated to a term t and the β-reduced term t' obtained from the application of t to $l_1 \ldots l_m$ is in $\mathcal{L}_\lambda$. Moreover, X is unified to t.

Definition 7.5 (progress-beta-dedup)*.* Given a β-`link` l_1 and second link $l_2 \in \mathbb{L}$, such that they share the same lhs. The two rhs are unified and a l_2 is removed from $\mathbb{L}$.

Definition 7.6 (progress-rigid-lhs)*.* Given a β-`link` with rigid lhs, the unification fails.

Lemma 7.7. `progress` *terminates*

Proof sketch. Let l a β-`link` in the store $\mathbb{L}$. If l is activated by *progress-beta-rigid*-rhs, then it disappears from $\mathbb{L}$ and `progress` terminates. Otherwise, the rhs of l is made by a variable applied to m arguments. At each activation of *progress-beta-$\mathcal{L}_\lambda$*, l is replaced by a new β-`link` l^1 having $m-1$ arguments. At the m^{th} iteration, the β-`link` l^m has no more arguments and is removed from $\mathbb{L}$. Note that at the m^{th} iteration, m new η-`link` have been added to $\mathbb{L}$, however, by lemma 5.15, the algorithm terminates. Finally *progress-beta-dedup* (resp. *progress-rigid*-lhs) also guarantees termination since it removes a link from $\mathbb{L}$ (resp. immediately fails).

E:funziona. per essere più precisi io parlerei di ordine lessicografico (tipico ordine ben fondato usato per dimostrare terminazione). Nl nostro caso è la tripla (argomenti extra dei beta, numero di beta, numero di eta).

D:da finire

□

Lemma 7.8 (Fidelity with β-`link`). *The introduction of* β-`link` *guarantees proposition 2.2 (*Simulation fidelity*)*

Proof sketch. Let $\mathbb{T}$ a unification problem and σ a substitution such that $\mathbb{T} \in \Diamond\mathcal{L}_\lambda$. If $\sigma\mathbb{T}$ is in $\mathcal{L}_\lambda$, then by definitions 7.3 and 7.4, the β-`link` associated to the subterm of $\mathbb{T}$ have been solved and removed. The unification is done between terms in $\mathcal{L}_\lambda$ and by lemma 5.16 fidelity is guaranteed. If $\sigma\mathbb{T}$ is in $\Diamond\mathcal{L}_\lambda$, then, by definition 7.6, the unification fails, as per the corresponding unification in $\mathcal{F}_o$. □

Example of progress-beta-$\mathcal{L}_\lambda$. Consider the β-`link` below:

$$
\begin{aligned}
\mathbb{P} &= \{\ X \simeq_o \lambda x.x \quad \lambda x.(Y \cdot (X \cdot x)) \simeq_o f\ \}\\
\mathbb{T} &= \{\ A \simeq_\lambda \lambda x.x \qquad\qquad B \simeq_\lambda f\ \}\\
\mathbb{M} &= \{\ Y \mapsto D^0 \quad X \mapsto A^0\ \}\\
\mathbb{L} &= \left\{ \begin{array}{ll} \vdash A =_\eta \lambda x.E_x & \vdash B =_\eta \lambda x.C_x \\ x \vdash C_x =_\beta (D \cdot E_x) & \end{array} \right\}
\end{aligned}
$$

Initially the β-`link` rhs is a variable D applied to the E_x. The first unification problem results in $\sigma = \{A \mapsto \lambda x.x\}$. In turn this instantiation triggers $\mathbb{L}_1$ by *progress-η-left* and E_x is assigned to x. Under this substitution the β-`link` becomes $x \vdash C_x =_\beta (D \cdot x)$, and by *progress-beta-$\mathcal{L}_\lambda$* it is replaced with the link: $\vdash E =_\eta \lambda x.D_x$, while C_x is unified with D_x. The second unification problem assigns f to B, that in turn activates the second η-`link` (f is assigned to C), and then all the remaining links are solved. The final $\mathcal{H}_o$ substitution is $\sigma = \{A \mapsto \lambda x.x, B \mapsto f, C_x \mapsto (f \cdot x), D \mapsto f, E_x \mapsto x, F_x \mapsto C_x\}$ and is decompiled into $\rho = \{X \mapsto \lambda x.x, Y \mapsto f\}$.

Example of progress-beta-rigid-rhs. We can take the example provided in section 7. The problem is compiled into:

$$
\begin{aligned}
\mathbb{P} &= \{\ X \simeq_o \lambda x.Y \quad (X \cdot a) \simeq_o a\ \}\\
\mathbb{T} &= \{\ A \simeq_\lambda \lambda x.B \qquad C \simeq_\lambda a\ \}\\
\mathbb{M} &= \{\ Y \mapsto B^0 \quad X \mapsto A^0\ \}\\
\mathbb{L} &= \{\ \vdash C =_\beta (A \cdot a)\ \}
\end{aligned}
$$

The first unification problems is solved by the substitution $\sigma = \{A \mapsto \lambda x.B\}$. The β-`link` becomes $\vdash C =_\beta ((\lambda x.B) \cdot a)$ whose rhs can be β-reduced to B. B is in $\mathcal{L}_\lambda$ and is unified with C. The resolution of the second unification problem gives the final substitution $\sigma = \{A \mapsto \lambda x.B, B \mapsto C, C \mapsto a\}$ which is decompiled into $\rho = \{X \mapsto \lambda x.a, Y \mapsto a\}$.

7.3 Relaxing definition 7.6 (*progress-rigid*-lhs)

Working with terms in $\mathcal{L}_\lambda$ is sometime too restrictive. There exists systems such as λProlog [10], Abella [5], which delay the resolution of $\Diamond\mathcal{L}_\lambda$ unification problems if the substitution is not able to put them in $\mathcal{L}_\lambda$.

$$\mathbb{P} = \{\ (X \cdot a) \simeq_o a \quad X \simeq_o \lambda x.Y\ \}$$

In the example above, $\mathbb{P}_1$ is in $\Diamond\mathcal{L}_\lambda$ and the object language cannot solve it, and, by proposition 2.2, the meta language neither. However, we can be more permissive, and relax **??**. This modification is quite simple to manage: we are introducing a new $\Diamond\mathcal{L}_\lambda$ progress rule, say *progress-beta-$\Diamond\mathcal{L}_\lambda$*, by which, if lhs is rigid and rhs is flexible, the considered β-`link` is kept in the store and no progression is done[2]. *progress-beta-$\Diamond\mathcal{L}_\lambda$* makes `occur-check-links` partial, since the check is possible only on links with a variable on the lhs. This means that we can have two links $\vdash X =_\beta Y \cdot a$ and $\vdash f \cdot X =_\beta Y \cdot a$ where the occur check does not throw an error. Note however, that the decompilation of the two links will force

[2] This new rule trivially guarantees the termination of progress

the unification of X to $Y \cdot a$ and then the unification of $f \cdot (Y \cdot a)$ to $Y \cdot a$, which fails by the occur check of $\simeq_\lambda$.

A second strategy to deal with problem that are in $\diamond\mathcal{L}_\lambda$ is to make some approximation. This is the case for example of the unification algorithm of Coq used in its type class solver [16]. The approximation consists in forcing a choice (among the others) when the unification problem is in $\diamond\mathcal{L}_\lambda$. For instance, in $X \cdot a \cdot b = Y \cdot b$, the last argument of the two terms is the same, therefore Y is assigned to Xa. Note that this is of course an approximation, since $\sigma = \{X \mapsto \lambda x.Y, Y \mapsto \_\}$ is another valid substitution for the original problem. This approximation can be easily introduced in our unification procedure, by adding new custom β-`link` progress rules.

Decompilation of β-`link` is possible by extending `commit-link` with new heuristics.

8 ACTUAL IMPLEMENTATION IN ELPI

In this paper we show a minimized example. The full code is there. But we also have to code things in Coq-Elpi.

The main difference between the presentation in the previous sections and the actual implementation for Coq is that the main loop hrun is replaced by the one of Prolog that chains calls to the unification procedure. In order implement the store of links we resort to Elpi's CLP engine and use constraints (suspended goals) to represent links, and constraint handling rules to implement progress operations involving more than one link.

finish

about the progress of 1 link:

```
link-eta L R :- suspend-condition L R Holes, !,
  declare_constraint (link-eta L R) Holes.
link-eta L R :-
  progress. % e.g. L = R.
```

about the progress of 2 links:

```
constraint link-eta {
  rule (N1 ▷ G1 ?- link-eta (uvar X LX1) T1) % match
    /  (N2 ▷ G2 ?- link-eta (uvar X LX2) T2) % remove
    |  (relocate LX1 LX2 T2 T2')             % condition
   <=> (N1 ▷ G1 ?- T1 = T2').                % new goal
}
```

Remark how the invariant about uvar arity makes this easy, since LX1 and LX2 have the same length. Also note that N1 only contains the names of the first link (while relocate runs in the disjoint union) and Elpi ensures that T2' can live in N1.

9 OTHER ENCODINGS AND RELATED WORK

One could ignore the similarity between $\simeq_o$ and $\simeq_\lambda$ and "just" describe the object language unification procedure in the meta language by crafting a `unif` routine and using it as follows in rule ($r3$):

```
decision X :- unif X (all A x\ app [P, x]), finite A,
  pi x\ decision (app [P, x]).
```

This choice would underuse the logic programming engine provided by the meta language since, by removing any datum from the head of rules, indexing degenerates. Moreover the unification procedure `unif` programmed in the meta language is likely to be an order of magnitude slower than one that is built-in.

Another possibility is to avoid having the application and abstraction nodes in the syntax tree, and use the ones of meta language, as in the following:

```
finite (fin N).
decision (nfact N NF).
decision (all A x\ P x) :- finite A, pi x\ decision (P x).
```

There are two reasons for dismissing this encoding. The first one is that in CIC it is not always possible to adopt it since the type system of the meta language is too weak to accommodate for the one of the object language. In CIC the lambda abstraction has to carry a type in order to make type checking decidable. Moreover CIC allows for functions with a variable arity, like the following example:

```
Fixpoint arr T n := if n is S m then T -> arr T m else T.
Definition sum n : arr nat n := ...
Check sum 2   7 8   : nat.
Check sum 3   7 8 9 : nat.
```

The type system of the λProlog is too stringent to accept this terms. The second reason is that the CIC encoding provided by Elpi is used for meta programming (extending) the Coq system, hence it must accommodate the manipulation of terms that are now know in advance (not even defined in Coq) without using introspection primitives such as Prologs's `functor` and `arg`. In this sense constants have to live in an open world, like the `string` data type used in the examples so far.

In the literature we could find related encoding of the Calculus of Constructions [2]. The goal of that work was to exhibit a logic program performing proof checking in CC and hence relate the proof system of intuitionistic higher-order logic (that animates λProlog programs) with the Calculus of Constructions. The encoding is hence tailored toward a different goal, and utilizes three relations to represent the equational theory of CC. Section 6 contains a discussion about the use of the unification procedure of the meta language in presence of non ground goals, but the authors do not aim at exploiting it to the degree we want.

sucks

cite isabelle's TC, that are baked in

10 CONCLUSION

Benefits: less work, reuse efficient ho unif (3x faster), indexing,

Future: tabling and static analysis (reuse for ML again).

Very little is Coq specific. Applies to all OL that are not a subsystem of HOL, or for ML that are used for meta programming.

APPENDIX

This appendix contains the entire code described in this paper. The code can also be accessed at the URL: https://github.com/FissoreD/paper-ho

Note that `(a infix b) c d` de-sugars to `(infix) a b c d`.

Explain builtin name (can be implemented by loading name after each pi)

11 THE MEMORY

```
kind addr type.
type addr nat -> addr.
typeabbrev (mem A) (list (option A)).

type set? addr -> mem A -> A -> o.
set? (addr A) Mem Val :- get A Mem Val.

type unset? addr -> mem A -> o.
